

## Economies that become part of Nature

Philip F Henshaw

**Ever Expanding the Circle**

Or

**Completing the Circle ?**

Any kind of project begins with searching for how to expand from a small starting point, and then in response to how that goes, and the limits of your time and resources, efforts change to searching for how to complete it. That's what's called a "[mind sized problem](#)"<sup>1</sup>, and can be

studied in terms of the universal sequence of developmental changes of direction of events that begin and end over time<sup>2</sup>.

For example, the "peak oil" phenomenon is a symptom of decreasing returns in a history of increasing search. It's been taken to the point where the economies are running out of the cheap energy resources they were built to use and have to [use-adapt to](#) more expensive ones. Continued economic growth now pushes up the price and undermines the existing capital of economic development that was build to use cheap energy. The pain of this is now evident, of course, but the pattern of diminishing returns was visible [a long time ago](#). It seems to have been in the 1950's (fig. 1) when increases in the search for new oil reserves began to have declining results.

In our search for energy, failing to read that signal had another major effect, making us ever more dependent on systems using an energy source that was running out. It remains more profitable to use up

shrinking supplies of cheap energy and sustain the growth of unsustainable systems. To convert the economies to sustainable resources the financial markets would need to invest in things that are relatively less profitable.

The general "[precautionary principle](#)"<sup>3</sup> to avoid [irreversible harm](#) applies here, [to](#) making sure to reserve the time and resources needed to complete what you begin [when it is harmful not to](#). In this case it's starting up an economic system that would soon run out of its "seed energy" [resource and not preparing for that](#). Our economic [development](#) steering mechanism, is tuned only for maximum current profits,

p.f. Henshaw

1

[thoughat present](#). [It-Development](#) both didn't respond to the clear signals to invest in sustainable resources decades ago, and even after two major energy shocks still finds it relatively unprofitable to do so.

[Examples of hHow both natural system economies and search & development projects people manage personally each](#) solve that same sort of problem [provide lest can be studied for insight one study how eThey display how](#) even free market systems can be responsive to their own limits and adapt promptly, rather than too late, to limits on their search strategies. There's a natural design principle that allows them to be [both](#) growth oriented [but to also-and also](#) gracefully complete their growth cycles to become sustainable. Then the question becomes how to teach our society to learn from nature's example. [It means learning from natural systems that are not equations, but search processes.](#)

As individuals we would [never intend to search for solutions causing us to unwittingly cross lines of conflict with others and](#) stumble into a war [by unwittingly crossing lines of conflict with others](#),

[or abuse credit and the search for profits to push our society into a global financial panic.](#)

Societies, however, very regularly get caught in these "[search traps](#)", [and](#). [The key to why is hidden if how we also](#) seemingly never learn from them. That puzzle is bound up with the deep mystery of why so many of mankind's most advanced

problem solving societies of the past ran into problems they couldn't solve and then collapsed and vanished<sup>4,5</sup>. In hindsight we may think we see exactly what happened, but still people seem unable to learn from it, [because it repeats](#).

In building a sustainable world it's very clear that we're using up all our affordable resources as fast as possible for growth, [for example](#). To our society's [choices for maximum profit](#) that's "logical", despite [not knowing how the economy could having no plan for surviving](#) on the expensive resources ahead. It's a lot like [in building a house, wasting using up all the lumber you have for building a house before](#)

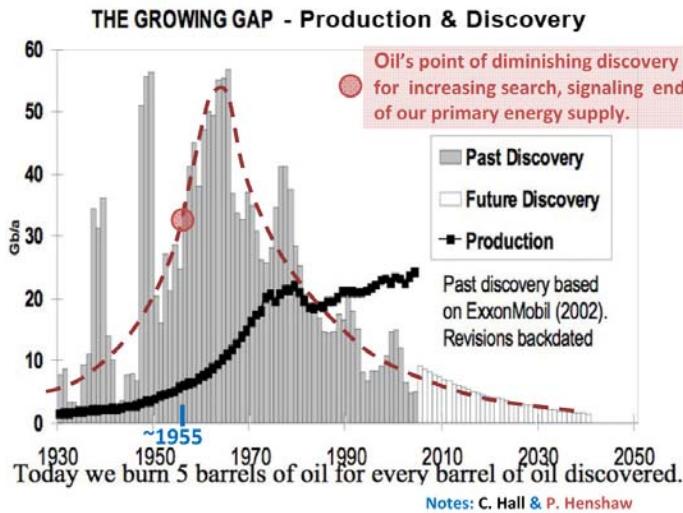

Fig. 1 History of oil discovery and production with projection - Laherre

getting putting on the roof ~~on~~. It leaves you with a new home that is unlivable. That's exactly what we're doing.

The blind spot of not preparing to finish what you start even extends to the popular alternative economic proposals for solving our erupting resource problems. They correct that symptom but ~~all still all~~ seem to contain the main problem that led to it. They describe how mankind could live comfortably within its limits physically, but don't change the economy's deep seated practices of continually multiplying its search for greater short term profits schemes to start but never finish. Our dependence on multiplying maximizing the growth of profits immediate profit is the core problem that makes keeps the system from living in a finite world impossible completing what it starts. The big profits in any developmental process are naturally in its beginnings, inherent in how searches for profits start with multiplying returns and only finish with diminishing ones.

The solution lies in understanding that investment is both the economy's natural search strategy for new directions, and what builds the new directions the economy takes. That, which makes makes investment decisions the economy's natural steering mechanism.

Investment is the economy's primary search strategy for new directions. It's what is physically responsible for steering the whole economic system, so it. That would carriesy a natural as well as a legal fiduciary responsibility for that. How to understand what that means, and apply it, is a question, but that principle seems to be the key.

The larger story of the natural search & development sequence is shown in fig. 2. A successful search path begins with a "seed resource" of some kind, and then proceeds by using products of the search to expand the search, by self-investment. That's the high profit phase of any search. Think of it as a business using its profits to expand grow. That "auto-catalytic" growth is ever more productive for a while. The turning point when new values and strategies come into play that becomes ever less productive is generally not so hard to see, if you're looking for it.

What's extremely hard to do is turn a whole social system that spent hundreds of years organizing itself around ever multiplying search and growing self-investment. The narrowing of options at the limits

pushes for growing returns investment choices into direct choices to ever shorter term strategies, turning away the system away from long term the ones it should be switching to. Having a functional fixation like that is like driving a car and seeing a right turn ahead, and realizing the steering system wheel only goes left. Just hoping that leaning toward the right seems to be will turn the car all the passengers can do, but is not likely to help.

Something needs to change the steering mechanism so an economy with a fixed design for multiplying start-up's can finish things, even imitating what both growth oriented natural systems and projects people manage personally demonstrate can be done gracefully. Natural system and personally managed searches also both take off with a run of growing multiplying successes. They then also remain responsive to the turning point of that success, however, reading it as a signal to complete their designs and come into balance with their environments.

Traditional economic theory, to the contrary, is that you can't have a growth turning point, and never run out off resources becoming unresponsive in total, resources because ever expanding searches will are

expected to always discover new resources to replace those being used up. By adding %'s to investment you add %'s to the resources you spend searching for more resources, so it all multiplies exponentially, for a while.

The theory works fine, in fact, and has been quite profitable for centuries, and would actually never fail in theory. The

expectation that it would continue only fails in reality. It's based on hindsight not foresight, and ignores that all physical systems have limits of predictability.

Continually using more of your resources to increase your search for more resources, to use up ever faster..., does seem to be the most profitable choice even as it runs out<sup>6</sup>. It automatically results in a whole system "tragedy of the commons"<sup>7</sup> though, as the economy becomes a "zero sum game" with ever more intense competition for declining resources.

It's very curious that people have hardly noticed that nature is simply full of systems that work quite like free market economies, and but don't have this

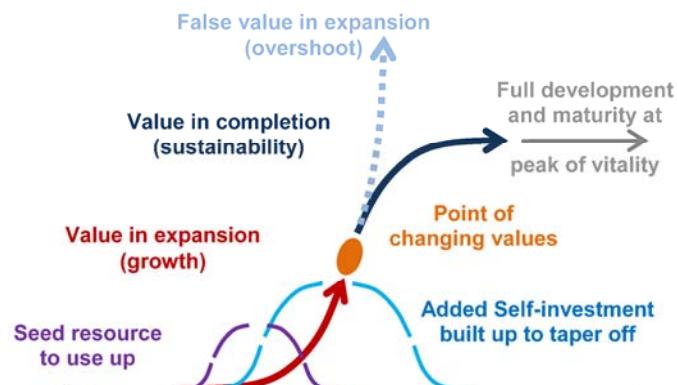

Fig. 2 – Developmental Search Plan, Whole System Business Model  
Starting Unfinished Things to then Perfect & Integrate Them

problem. Both populations of cells that cooperate as organisms and populations of organisms that cooperate as communities, develop systems of cooperation by linking their complementary differences, just like the parts of economies do. They also usually common element is the parts organize their economic lives around the exchange of products and services through a medium of free exchange, and start the development of those links starting -with a period of growth by self-investment.

Most often they When they don't climax that growth by letting their growth it create destabilizing internal conflicts and environmental tragedies, despoiling for their own niches and collapsing in exhaustion they tend to stabilize. Successful organisms and communities They somehow "form a system" and stabilize at the peak of their vitality. They, and become part of their environments. It seems possible that if we turned our search interests toward how they do that, it might provide us the escape from our present headlong rush in the opposite direction.

Scientists may often say "there are no systems, just pressures", and dismiss the idea. That might come from the reliance of science on using equations to represent natural systems with rules for a balance of with pressures rules. The big difference between natural system economies and equations is that natural system economies have living parts, that are actively learning from their environments as they go.

Representing the parts of economies as numeric variables, controlled by theoretical pressures from other variables, hides the behavior of the parts as living things. It hides their self-animated individual and group, learning and responses as living things. The real parts of economies are largely self-animating, actively exploring to their surroundings and responding to what each other learn. So local rules develop inside local groups communities of parts. Outside pressures would be unable to predict or control them that. Because they have learning parts economies are opportunistic systems, not deterministic systems.

The dilemma for science has been its need to have its terms well defined. What learning systems might discover as they explore their environments is not definable. Science can still start by learning how to identify where such learning systems are located and how to tell when they are taking new directions, though. Peak rates of learning and the time when rates of change reverse directions are often possible to locate quite precisely. That kind of information, hints and warnings of other things changing direction, is what one usually uses to guide steering activities anyway. It leads to better questions about what other things are the uncontrolled learning changes around you

learning, some that can be answered with confidence, even even while also while knowing you don't know much about them displaying one's ignorance of them too.

Fortunately one can start by learning from study this in the successful search & learning systemssystems you're part of and already quite familiar with. A freshwater pond economylogy uses the water to link populations of widely varying species that create their own niches and exchange complementary services. Each one benefits and contributes to the resource uses of the whole. - Each They seem to do their parts by organism resourcefully using what the others abandon or leave unintended create but find useless. All are engaged in foraging and dodging, being resourceful with what the others leave unintended. they also without crossing avoid lines of conflict. That active learning searching for advantages that fit by the parts makes the system and its parts fit each other and their environment.

An office workplace also houses a local natural system economy. It's where employees exchange their complementary needs and abilities. It's a place where groups can work sort out with each other how to do their jobs, and create an organization that works as a whole through mutual guidance. A manager may be able to tell if you're doing your job or not, but they rarely know how you do it themselves, since it's each individual's job to invent how to do it in cooperation with others.

Families are also natural system economies in their own right, organized around their own internal networks for exchanging complementary goods and services. They operate as a whole in backing up each member in their interactions with other environments.

These are examples of the kinds of uncontrolled natural system economies that are often very good at taking care of themselves. They're also quick to take advantage of growth opportunities without letting blind pursuit of them destabilize themselves or their environments.

There are, of course, also plenty of examples of individual or group development strategies, fed by excessive or ignorant ambition, that overshoot their own talents and resources. An overzealous suitor is a good example, responding to aggressively to openings for advance and getting rejected. Growth opportunities that start that way ignore the environment they need to fit with generally fail, and so don't stay around for us to study. We all probably have vivid memories of being part of them, whether having a part in "blowing "the big account" at the office, or watching as someone else ignores all the warnings and gets in deep trouble. The general precautionary principle for searches is to watch your environment for

lines of conflict. I've sometimes called it "the principal principle of cybernetics", the central idea of "steering". If you're aware of it, it's actually half the fun.

As mentioned above, the popular models for sustainable free market economies propose limiting our physical impacts on the earth, but not aomit a solution for our investment culture and procedures that produce-rely on an multiplying the search for quick profits.

The "economic democracy" idea proposed in World Watch this month by David Schweickart<sup>8</sup>, for example, has many interesting ideas. His model for democratically run businesses would still have them using the same rules for growing investment that cause private money choices to drive ever multiplying competition, though. Having that flaw also puts his scheme in very good company. The same omission mars seemingly all the popular alternate economic models, such as the "transformative technology" ideas of Paul Hawken and the Lovins's in *Natural Capitalism*<sup>9</sup>, the "transformative governance" or "sustainable development" ideas behind the models of Herman Daly<sup>10</sup> in *Beyond Growth* or Gus Speth in *The Bridge at the Edge of the World*<sup>11</sup> or H.T Odum in *A Prosperous way down*<sup>12</sup>. It's even in the critically well-received *Prosperity without Growth*<sup>13</sup> proposal, by Tim Jackson of the U.K.'s Sustainable Development Commission.

The problematic rule of financial accumulation is to assure a maximum regular return to continually add to future investments. There's-The secret is that there is nothing wrong with either of those two steps in the rule, by themselves. The problem is connecting them. Doing both results in requiring all investments to contribute to ever multiplying investments. It creates an economy that pushes us to search for new resources and talents ever more frantically to survive. It keeps us from turning our attention to using our resources to secure our place on earth and become a creative part of nature.

Together those two parts of the rule of accumulation, to make rather fairly sure bets and then add your winnings to your bets, turns any system into something like a Ponzi scheme. It raises the stakes exponentially by multiplying competitive stimulus and searches for profits till something breaks. That kind of growth of competition in a steady-state economy would drive increasingly

The Sorcerer's Apprentice driven mad!

productive people to take ever more from everyone else, naturally. It's not the values of the people doing it, but the system they're unwittingly caught up in!

The historical "solution" to that for centuries was economic growth. With continual multiplying consumption of the earthresources the unfair shares taken by some become-are more tolerable to others. Of course, using that growth solution as the economy runs into natural limits gives us ever intensifying competition over ever shrinking resources, a different story. That's what we're now doing. It's enough to drive any "well mannered" Sorcerer's Apprentice<sup>14</sup> caught up in it completely crazy!

There's an elegant certainty that points to a solution. It was first discovered by JM Keynes and then further studied by Kenneth Boulding. It helps me point to the riddle of how natural-system economies can be both growth oriented and remarkably so good at taking care of themselves as part of nature too. Perhaps those who read chapter 16 in Keynes' General Theory<sup>15</sup> or Boulding's last chapter in A Reconstruction of Economics<sup>16</sup>, or my papers, were embarrassed to not quite understand or hesitant to ask the noticeable "dumb questions" raised. The question is how to arrive at "peak money", and plan for the natural end of automatic concentrating wealth. Money is what we use to measure the value of physical thingswealth and obtain permission to use themit, so money needs to grow only as fast as sustainable physical wealth does.

The way Keynes put it (para.), if you accept that real wealth has natural limits the simple paradox is that either a) investment stops growing because conditions get so bad that returns on investments don't materialize, or b) healthy returns are earned by

investments, but instead of being accumulated, they are recycled as spending. Either one-way serves to brings about "peak money" at the time of peak wealth, and there is logically is no other choice.

The default choice is (a), and there is no present mechanism for or likelihood of (b). In our economy money grows in proportion to money and real wealth in proportion to our resourcefulness with the earth. It appears that successful economies necessarily end their own self-investment growth cycles as a precaution. It appears to create resources for other things while

avoiding the-rather than submit to pressures-conflicts

~~that cause~~~~that would cause their~~ investments to fail. It appears to be a “win win” capital preservation strategy. I hope this is a simpler way to say it, since clearly no one listened to Keynes or Boulding. The Getting it right~~matter~~ is indeed a question of life or death for our hopes for the earth.

When presented with an approaching certainty, the question is how to respond in a smooth and timely way. Steering problems are like that. If you see a necessity for a change in plans, a curve in the road, you do two things. One is to start thinking about how to turn. The other is to start looking for when. I like to use the analogy of paddling a canoe, skiing down a mountain, or driving a race car. When you see a turn coming you first mentally prepare a move and then wait for the earliest opportunity to do it smoothly. That minimizes the energy and danger, and makes it fun. It also upstages nature’s alternate solution for responding to the-a coming turn too late, fishtailing to capsize, tumble or crash.

How to phase in workable rules to steer profitable investment toward becoming sustainable and maintain good returns is a question. The end is easy to define conceptually, at natural limits ~~to~~-assure that enough investment is spent to no longer continue to multiply faster than real wealth. The first thing is for other~~More~~p people need to explore the questions of how to do it and when. One practical choice would be to qualify the tax status of investment earnings., and If instead of taxing returns it could just require the divestment of returns. If good measures are available, that allow reinvestment of in any earnings from industries that is~~are not~~ driving the economy in unsustainable directions. You could begin with small fractions, guided by the use of whole system scientific measures of sustainability. As you feel your way along you’d keep in mind the other main “precautionary rule”, that you’d allow exceptions only if they don’t invalidate the main rule.

This is a kind of “biomimicry” for how natural systems prosper despite having limits to growth. It would be a learning process. The intent is to learn how to switch to the natural way of completing things that last and integrate with their environments. I think our long history of “being at war with nature” no longer seems profitable. Finding ourselves working ever harder at a clearly impossible task seems like a very good time to quit.

It’s also an idea for how to avoid the fatal traps for modern civilization so well described by Joe Tainter in *The Collapse of Complex Societies*<sup>17</sup> among and others like Jared Diamond in Collapse<sup>18</sup>. The long history of complex societies collapsing seems clearly associated with societies of proficient problem solvers running into diminishing returns for their own methods

of solving problems, and ~~that~~becoming a ~~traped~~trapped. It’s a way for them to get tricked into turning their best solutions into their own worst problems~~s~~. Diminishing returns for any direction of development is as reliable a principle as gravity. It’s a passive cause, part of what lets it “sneak up on us”, but apparently a very real hazard.

One of the crazy things it has pushed us into is using efficiency to reduce resource use and sustain growth at the same time. , The invariably which accelerates multiplies the use of other resources use, which usually more than defeats and voids the original purpose of the effort. What we really need is an environment that is searching for how to make things last, aa maturing economy rather an ever immaturely erupting economy., so the~~Then the~~ efficiencies we devise can would apply to making something lasting things work ever more smoothly.

As far as my own contribution, I have various things linked from my Synapse9.com website archive.

The main source for of learning about the subject how to make these switches seems likely to be each individual’s own original observations about how how searches for lasting change in their own lives begin and end. Those are the things in which at’s where you can really begin to see how it’s its really the environment of the change that is first growing and then maturing, and the purposes and values of the searcher that follows them.

Every kind of project whether making dinner for family or friends, or building a business career in business and rising to the top, begins with expanding your search and ends with perfecting it, the They’re two different kinds of accumulation that go along with starting and finishing things. They’re periods of outward and then inward growth, generating a framework and then completing it with adding refinements, not an equation but a learning process. Some version of that pattern seems observable in all processes of lasting developmental change as they begin and end, whether planned or unplanned. We Everyone knows a lot about it already, is really the point. It’s very natural.
